

Main results of lecture 1:

Kondo Model:

$$H = \sum_{k\sigma} \epsilon_k c_{k\sigma}^\dagger c_{k\sigma} + J \sum_{kk'\sigma\sigma'} (c_{k\sigma}^\dagger \frac{1}{2} \vec{\sigma}_{\sigma\sigma'} c_{k'\sigma'}) \cdot \vec{S} \quad (1)$$

Spin-flip scattering:

enhanced at low temp:

$$T \lesssim T_K = D \exp[-\frac{1}{N J}]$$

$$\Rightarrow \text{ground state} = \text{spin singlet} \quad (\downarrow\uparrow) \quad (2)$$

Scattering phase shifts at $T = 0$:

$$\delta_\uparrow(0) = -\delta_\downarrow(0) = \pi/2 \quad (3)$$

How do magnetic moments form in metals?

Answer provided by "Anderson impurity model" (AM) [1961], relevant also to describe transport through quantum dots, which also show Kondo effect [1998].

Single-impurity Anderson model

AM2

Anderson, Phys. Rev. 124, 41 (1961); Hewson, "The Kondo Problem to Heavy Fermions", Cambridge (1993).

Conduction band:

(flat DOS, "wide-band limit": $D \gg \text{all other scales}$)

$$H_{\text{band}} = \sum_{k\sigma} \epsilon_k c_{k\sigma}^\dagger c_{k\sigma} \quad (1)$$

Localized impurity level:

$$H_{\text{loc}} = \sum_{\sigma} (\epsilon_d + \underbrace{\sigma \mu_B}_{=0}) d_{\sigma}^\dagger d_{\sigma} + U \hat{n}_{d\uparrow} \hat{n}_{d\downarrow} \quad (2)$$

Hybridization:

[usual convention:
 $v_k = v = \text{real}$]

$$H_{\text{hyb}} = \sum_{k\sigma} v_k [c_{k\sigma}^\dagger d_{\sigma} + \text{h.c.}] \quad (3)$$

Level width:

(from golden rule)

$$\Gamma = \pi v^2 \quad (4)$$

Level occupancy:

$$n_d = \langle n_{d\uparrow} + n_{d\downarrow} \rangle$$

Conductance anomalies for quantum dot in "Kondo regime"

AM3

Linear conductance:
Odd Coulomb valleys
become Kondo plateaus

Fixed gate voltage:
Anomalous T- and V-
dependence

Conductance anomalies: real data

AM4

Weak Kondo effect

Goldhaber-Gordon et al., Nature **391**, 156

Strong Kondo effect

van der Wiel et al., Science **289**, 2105 (2000)

Ideal Kondo effect

van der Wiel et al., Science 289, 2105 (2000)

- Beautiful Kondo plateau observed
- T-dependence follows universal form when scaled by T_K
- This allows determination of T_K
- Observed dependence of T_K on ϵ_d agrees with theoretical prediction:

$$\log T_K = c_1 \epsilon_d (\epsilon_d + U) + c_2$$

When does "Kondo plateau" arise?

Occurs for

$$T \rightarrow 0 \quad (T \ll T_K)$$

and when

$$N_d \simeq 1 \text{ (odd)} \Rightarrow \text{localized spin}$$

Loc. spin + cond. band :

$$\text{Kondo model} \Rightarrow \text{Spin-flip scatt. !!}$$

Spin-flip processes occur via virtual intermediate states.

$$\text{Effective spin-flip rate: } \nu \frac{v^2}{\epsilon_d + U} - \frac{v^2}{\epsilon_d} = - \frac{U r^2 / \pi}{\epsilon_d (\epsilon_d + U)} = : J \quad (>0)$$

(1)

Schrieffer-Wolff transformation

Phys Rev 149, 491 (1966)

AM 7

$$H_{AM} = \underbrace{H_{band} + H_{loc}}_{H_0} + \underbrace{H_{yb}}_{H_1 = O(v)} \quad \text{Idea: seek effective } \tilde{H} \text{ in subspace of } n_d = 1$$

Try unitary transf.: $\tilde{H} = e^A H e^{-A}, \quad \text{with } A^\dagger = -A \quad (1)$

A has pert. exp. in v : $A = 0 + O(v) + O(v^2) + \dots \quad (2)$

Expand $\tilde{H}$: $\tilde{H}^{(2)} = (H_0 + H_1) + [A, H_0 + H_1] + \frac{1}{2}[A, [A, H_0 + H_1]] \quad (3)$

Demand: $\tilde{H}$ contains no $O(v)$: $H_1^{(3)} = -[A, H_0], \quad (4) \Rightarrow \tilde{H}^{(3)} = H_0 + \frac{1}{2}[A, H_1] + O(v^3) \quad (5)$

check algebra yourself!

(5) is satisfied by: $A = \sum_{k\sigma} v \left[\frac{1}{\epsilon_k - \epsilon_d} c_{k\sigma}^\dagger d_\sigma + \frac{U}{(\epsilon_d - \epsilon_k)(\epsilon_d + U - \epsilon_k)} d_{-\sigma}^\dagger d_{-\sigma} c_{k\sigma}^\dagger d_\sigma \right] - h.c. \quad (6)$

Effective Hamiltonian for $n_d = 1$ yields Kondo model

potential scattering

AM 8

(7.5) yields:

$$\tilde{H}|_{n_d=1} = \sum_{k\sigma} \epsilon_k c_{k\sigma}^\dagger c_{k\sigma} + \sum_{kk'} \tilde{V}_{kk'}^{(2)} \vec{S}_{kk'} \cdot \vec{S} + (c_k^\dagger c_{k'} - \text{term}) \quad (1)$$

local spin operators:

$$S^z = \frac{1}{2}(d_\uparrow^\dagger d_\uparrow - d_\downarrow^\dagger d_\downarrow), \quad S^+ = d_\uparrow^\dagger d_\downarrow, \quad S^- = d_\downarrow^\dagger d_\uparrow \quad (2)$$

$$:= \frac{1}{2} \begin{pmatrix} 0 & 0 \\ 0 & -1 \end{pmatrix}, \quad := \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad := \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}$$

conduction band spin operators:

$$\vec{S}_{kk'} = \frac{1}{2} \sum_{\sigma\sigma'} c_{k\sigma}^\dagger \vec{\sigma}_{\sigma\sigma'} c_{k'\sigma'} \quad (3)$$

coupling:

$$\tilde{V}_{kk'}^{(2)} = \frac{-\frac{1}{2} \tilde{V}_k \tilde{V}_{k'} U}{(\epsilon_d - \epsilon_k)(\epsilon_d + U - \epsilon_k)} \xrightarrow{|\epsilon_k|, |\epsilon_{k'}| \ll |\epsilon_d|, |\epsilon_d + U|} \approx \frac{\tilde{V}_{kk'}^2 U}{|\epsilon_d| |\epsilon_d + U|} =: J_{kk'} \quad (4)$$

Low-en. properties of AM for $n_d = 1$ described by KM:

$$H_{Kondo} = H_{band} + J \sum_{\mu\mu'} \vec{S}_{\mu\mu'} \cdot \vec{S}_{\mu\mu'} \quad (6)$$

$su(2)$ symmetric!

Eff. Kondo temp:

(observed: see AM 5!)

$$T_K = D e^{-\frac{1}{NJ}} \stackrel{(4)}{=} D \exp\left[-\frac{\pi |\epsilon_d| |\epsilon_d + U|}{rU}\right] \quad (7)$$

agrees with Bethe Ansatz, except for prefactor

Single-level quantum dot with two leads

Pustilnik, Glazman, PRL 87, 216601 (2001)

AM9

Recent review: "Nanophysics: Coherence and Transport," eds. H. Bouchiat et al., pp. 427-478 (Elsevier, 2005).

lead index:

$$\alpha = L, R$$

Two-lead Hamiltonian:

$$H = \sum_{k\alpha\sigma} \varepsilon_k c_{k\alpha\sigma}^\dagger c_{k\alpha\sigma} + \sum_{k\alpha\sigma} v_k^\alpha c_{k\alpha\sigma}^\dagger d_\sigma + \text{h.c.} + H_{\text{loc}} \quad (1)$$

"H₂ band"

Schrieffer-Wolff
as before, with

$$\sum_k v_k \rightarrow \sum_{k\alpha} v_k^\alpha (\dots)^\alpha \quad (2)$$

Effective Hamiltonian
for nd = 1:

$$H_{\text{Kondo}}^{\text{scat.}} = \sum_{\alpha\alpha'} \left(- \frac{v_{kF}^\alpha v_{kF}^{\alpha'} U}{\varepsilon_d(\varepsilon_d + U)} \right) \left(\sum_{k\alpha\sigma} c_{k\alpha\sigma}^\dagger \vec{\sigma}_{\sigma\sigma'} c_{k\alpha\sigma} \right) \cdot \vec{S} = \sum_{\alpha\alpha'} \underbrace{J_{\alpha\alpha'}}_{\vec{S}_{\alpha\alpha'} - \vec{S}} \cdot \vec{S} \quad (3)$$

Tr(J $\vec{S}$)

Coupling matrix:

$$J_{\alpha\alpha'} = \tilde{c} \begin{bmatrix} v_L^2 & v_L v_R \\ v_R v_L & v_R^2 \end{bmatrix}, \quad \text{with } v_\alpha = v_{kF}^\alpha, \quad \tilde{c} = \frac{-U}{\varepsilon_d(\varepsilon_d + U)} \quad (4)$$

Determinant:

$$\det J_{\alpha\alpha'} = \tilde{c}^2 [v_L^2 v_R^2 - (v_L v_R)^2] = 0 \quad \text{one eigenvalue} = 0 \quad (5)$$

Diagonalization of coupling matrix J

AM10

J is diagonalized by:

$$W = \begin{bmatrix} \cos \theta & \sin \theta \\ -\sin \theta & \cos \theta \end{bmatrix}, \quad \tan \theta = -v_R/v_L \quad (1)$$

diagonal form:

$$\tilde{J} = W J W^\dagger = \begin{bmatrix} J_1 & 0 \\ 0 & J_2 \end{bmatrix} = \begin{bmatrix} \tilde{c}(v_L^2 + v_R^2) & 0 \\ 0 & 0 \end{bmatrix} \quad (2)$$

Rotate basis:

$$\psi_{k\gamma\sigma} = \sum_{\alpha} c_{k\alpha\sigma} W_{\alpha\gamma} \quad (3)$$

$\sum_{k\alpha\sigma} (\psi_{k\alpha\sigma}^\dagger \vec{\sigma}_{\sigma\sigma'} \psi_{k\alpha\sigma})$

$$\tilde{H}_{\text{Kondo}}^{\text{scat.}} \stackrel{(9.2)}{=} \text{Tr} \left[\underbrace{W^\dagger J W}_{\tilde{J}} \underbrace{W^\dagger \vec{S} W}_{\vec{S}_1} \right] \cdot \vec{S} = J_1 \vec{S}_1 \cdot \vec{S} \quad (4)$$

J-diagonal Kondo
Hamiltonian:

$$H = \sum_{k\gamma\sigma} \varepsilon_k \psi_{k\gamma\sigma}^\dagger \psi_{k\gamma\sigma} + J_1 \vec{S}_1 \cdot \vec{S} \quad (5)$$

Important conclusion:

One mode yields Kondo-Hamiltonian, other mode decouples completely!

Comment: for multilevel AM, coupling matrix is more complicated: $v_k^\alpha c_{k\alpha\sigma}^\dagger d_{j\sigma}$

Then J2 can be nonzero, because $\det J_{\alpha\alpha'} \propto \sum_{j,j'} (v_j^L v_{j'}^R - v_j^R v_{j'}^L)^2 \neq 0 \quad (6)$

Conductance through (many-level) QD with 2 leads

AM11

Consider $T=0$, $B \neq 0$ but $\rightarrow 0$
which ensures non-degenerate ground state

lead index: $\alpha = L, R$

Then incident electrons experience only potential scattering, described by 2×2 S-matrix:

$$S_{\sigma, \alpha \alpha'}^{(0)} = W^\dagger D_\sigma W, \quad D_\sigma = \begin{pmatrix} e^{i\delta_{1\sigma}} & 0 \\ 0 & e^{i\delta_{2\sigma}} \end{pmatrix} \quad (1)$$

same as in (10.1)

Phase shifts:

$$\delta_{\gamma\sigma}, \quad \text{with } \gamma = 1, 2, \quad \sigma = \uparrow, \downarrow$$

Landauer formula
for conductance:

$$G(T=0) = \frac{e^2}{h} \sum_{\sigma} |S_{\sigma, RL}^{(0)}|^2 = G_0 \frac{1}{2} \sum_{\sigma} \sin^2(\delta_{1\sigma} - \delta_{2\sigma}) \quad (2)$$

Prefactor:

$$G_0 = \frac{2e^2}{h} \sin^2 \frac{\pi}{2} \stackrel{(10.1)}{=} \frac{2e^2}{h} \frac{4(v_L v_R)^2}{(v_L^2 + v_R^2)^2} = \frac{2e^2}{h} \text{ if } v_L = v_R \quad (3)$$

Important conclusion:

$T = 0$ conductance is determined purely by phase shifts!

Conductance through 1-level QD with 2 leads

AM12

For 1-level AM:

$$J_2 \stackrel{(10.2)}{=} 0, \quad \rightarrow \delta_{2\sigma} = 0 \quad (1)$$

From lecture 1, (K9.4):

$$\text{at } T=0, \quad \delta_{1\uparrow} = -\delta_{1\downarrow} = \pi/2 \quad (2)$$

Conductance at $T=0$:

$$G(T=0) \stackrel{(11.2)}{=} G_0 \frac{1}{2} \sum_{\sigma} \sin^2(\delta_{1\sigma} - \cancel{\delta_{2\sigma}}^{\pi/2}) = G_0 \quad (3)$$

for symmetric couplings ($v_L = v_R$)

$$= \frac{2e^2}{h}$$

= "unitarity limit", maximal possible value,
as though channel were completely open! (4)

Local Green's function:

$$G_{d\sigma}^R(\omega) = \int_0^\infty dt e^{-i\omega t} (-i) \langle \{d_\sigma(t), d_\sigma(0)\} \rangle$$

Spectral function =
local density of states
(LDOS):

$$A_{d\sigma}(\omega) = -\frac{1}{\pi} \text{Im} G_{d\sigma}^R(\omega) = \gamma_{loc}(\omega) = \rho(\omega)$$

For $T < T_K$, LDOS develops Kondo resonance...
which is observed directly in V-dep. of G (see AM4)

Numerical Renormalization Group
calculations by Michael Sindel, 2004
